Moscow International Workshop ACM ICPC, MIPT, 2015

▲□▶ ▲□▶ ▲□▶ ▲□▶ = 三 のへで

The problem regarded representing P dollars given a certain amount of 1, 2, 5, 10, 20, 50, 100, 200, 500, 1000 and 2000-dollar coins (or banknotes), while maximizing total number of coins used.

◆□▶ ◆□▶ ◆□▶ ◆□▶ □ のQ@

The problem regarded representing P dollars given a certain amount of 1, 2, 5, 10, 20, 50, 100, 200, 500, 1000 and 2000-dollar coins (or banknotes), while maximizing total number of coins used.

Observation

Denote T total amount of dollars we have. Obtaining P dollars using the most number of coins is the same as taking T - P using the least number of coins and leaving them out. In the following we discuss the problem of representing S using minimal amount of coins.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ●

A. Too Rich

Example (A simpler case)

Consider a set of denominations $d_1 < \ldots < d_k$ such that every

denomination divides the previous one: $d_{i+1}: d_i$ for all $i \in [1; k-1]$. Can we come up with an easy solution for the same problem?

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ●

Example (A simpler case)

Consider a set of denominations $d_1 < \ldots < d_k$ such that every

denomination divides the previous one: $d_{i+1}: d_i$ for all $i \in [1; k-1]$. Can we come up with an easy solution for the same problem?

Greedy algorithm for the simpler case

In this case a greedy algorithm works: take maximal amount of d_k -dollar coins such that the sum does not exceed S, then take maximal amount of d_{k-1} -dollar coins, and so on. If the total amount of money taken this way is S, then the representation is minimal, otherwise no representation is possible.

A

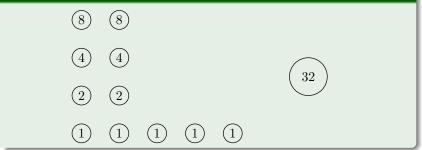

00000

Proof for the greedy algorithm

Suppose that $c_1d_1 + \ldots + c_jd_j \ge d_{j+1}$ for some integer non-negative c_j . Then we can choose integer non-negative c'_j such that $c'_j \le c_j$ and $c'_1d_1 + \ldots + c'_jd_j = d_{j+1}$. This can be done by induction: take maximal possible amount of d_j -dollar coins, and represent the rest using first j - 1 denominations (the rest amount is divisible by d_j). Now, consider any representation of $P = c_1d_1 + \ldots + c_kd_k$. If c_k is

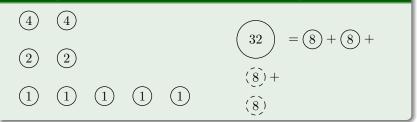

Now, consider any representation of $P = c_1 a_1 + \ldots + c_k a_k$. If c_k is not maximal possible, choose a subset of smaller coins with sum d_k and replace them with a single coin; repeat until the sum of smaller coins becomes less than d_k . So on for smaller coins. Μ

Example (Choose a subset with sum of exactly 32) =(8)+(8)+32(4) +(1)(1)(1)(1)(1)(2) 2 (2)+ (2)

▲□▶ ▲圖▶ ▲臣▶ ▲臣▶ 三臣 - のへ⊙

(1)

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ ―臣 …の�?

In the actual problem the divisibility condition does not hold: 20 does not divide 50, and 200 does not divide 500.

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ 三臣 - のへで

In the actual problem the divisibility condition does not hold: 20 does not divide 50, and 200 does not divide 500. However, the greedy approach can be slightly modified to work here. Suppose that on some step of the greedy algorithm the maximal number of d_i -dollar coins that we can take is X.

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ●

A. Too Rich

In the actual problem the divisibility condition does not hold: 20 does not divide 50, and 200 does not divide 500. However, the greedy approach can be slightly modified to work here. Suppose that on some step of the greedy algorithm the maximal number of d_j -dollar coins that we can take is X. Then, there is a minimal representation such that the number X' of d_j -dollar coins we take is at least X - 1, because if X' is at most X - 2, we can always replace a subset of smaller coins with a total amount of $2d_j$ with two d_j -dollar coins; the existence of this subset if proved similarily to greedy solution analysis.

In the actual problem the divisibility condition does not hold: 20 does not divide 50, and 200 does not divide 500.

However, the greedy approach can be slightly modified to work here. Suppose that on some step of the greedy algorithm the maximal number of d_j -dollar coins that we can take is X. Then, there is a minimal representation such that the number X' of d_j -dollar coins we take is at least X - 1, because if X' is at most X - 2, we can always replace a subset of smaller coins with a total amount of $2d_j$ with two d_j -dollar coins; the existence of this subset if proved similarily to greedy solution analysis.

Thus, the algorithm that recursively tries X and X - 1 for the number of largest coins will always give an optimal answer. Without any optimizations this performs $\sim 2^9$ operations per test, which works fast enough.

Let f(n) be the number of pairs $0 \le a, b < n$ such ab is not divisible by n, and $g(n) = \sum_{d|n} f(d)$. Find g(n).

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ 三臣 - のへで

Let's start with f(n). $f(n) = n^2 - h(n)$, where h(n) is the number of pairs $0 \le a, b < n$ such that ab : n.

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ 三臣 - のへで

в 000 B. Count $a \times b$

C

Let's start with f(n). $f(n) = n^2 - h(n)$, where h(n) is the number of pairs $0 \leq a, b < n$ such that ab n. Factorize *n*: $n = p_1^{\alpha_1} \dots p_k^{\alpha_k}$. Chinese remainder theorem implies that h(n) is multiplicative: $h(n) = h(p_1^{\alpha_1}) \dots h(p_k^{\alpha_k})$.

A

Let's start with f(n). $f(n) = n^2 - h(n)$, where h(n) is the number of pairs $0 \le a, b < n$ such that ab:n. Factorize $n: n = p_1^{\alpha_1} \dots p_k^{\alpha_k}$. Chinese remainder theorem implies that h(n) is multiplicative: $h(n) = h(p_1^{\alpha_1}) \dots h(p_k^{\alpha_k})$. Find $h(p^{\alpha})$. For $0 \le a < p^{\alpha}$ let d(a) be the maximal power of pdividing a (set $d(0) = \alpha$ by definition). For any given a and b: М

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ●

$$ab p^{\alpha} \iff d(a) + d(b) \ge \alpha$$

B. Count $a \times b$

в

000

A

Let's start with f(n). $f(n) = n^2 - h(n)$, where h(n) is the number of pairs $0 \le a, b < n$ such that ab:n. Factorize n: $n = p_1^{\alpha_1} \dots p_k^{\alpha_k}$. Chinese remainder theorem implies that h(n) is multiplicative: $h(n) = h(p_1^{\alpha_1}) \dots h(p_k^{\alpha_k})$. Find $h(p^{\alpha})$. For $0 \le a < p^{\alpha}$ let d(a) be the maximal power of pdividing a (set $d(0) = \alpha$ by definition). For any given a and b: М

$$ab p^{\alpha} \iff d(a) + d(b) \ge \alpha.$$

For any $0 \le k \le \alpha$, the number of *a*'s such that $d(a) \ge k$ is exactly $p^{\alpha-k}$. Thus, we obtain the formula:

$$h(p^{\alpha}) = \sum_{k=0}^{\alpha-1} ((p^{\alpha-k} - p^{\alpha-k-1})p^k) + p^{\alpha} = \alpha p^{\alpha} - (\alpha-1)p^{\alpha-1}.$$

Now,
$$g(n) = \sum_{d|n} f(n) = \sum_{d|n} d^2 - \sum_{d|n} h(d) = s_2(n) - H(n).$$

Now,
$$g(n) = \sum_{d|n} f(n) = \sum_{d|n} d^2 - \sum_{d|n} h(d) = s_2(n) - H(n).$$

Let $n = p_1^{\alpha_1} \dots p_k^{\alpha_k}$. Then

$$s_2(n) = \prod_{i=1}^k \sum_{j=0}^{\alpha_i} p_i^{2j}.$$

▲□▶ ▲□▶ ▲目▶ ▲目▶ 目 のへの

B. Count $a \times b$

B 00●

Now,
$$g(n) = \sum_{d|n} f(n) = \sum_{d|n} d^2 - \sum_{d|n} h(d) = s_2(n) - H(n).$$

Let $n = p_1^{\alpha_1} \dots p_k^{\alpha_k}$. Then

$$s_2(n) = \prod_{i=1}^k \sum_{j=0}^{\alpha_i} p_i^{2j}.$$

Since h(n) is multiplicative, H(n) is multiplicative too:

$$H(n) = \prod_{i=1}^{k} \sum_{j=0}^{\alpha_i} h(p_i^j) = \prod_{i=1}^{k} \alpha_i p_i^{\alpha_i} = n \prod_{i=1}^{k} \alpha_i.$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ 三三 - のへで

B. Count $a \times b$

C

в

000

Now,
$$g(n) = \sum_{d|n} f(n) = \sum_{d|n} d^2 - \sum_{d|n} h(d) = s_2(n) - H(n).$$

Let $n = p_1^{\alpha_1} \dots p_k^{\alpha_k}$. Then

$$s_2(n) = \prod_{i=1}^k \sum_{j=0}^{\alpha_i} p_i^{2j}.$$

М

Since h(n) is multiplicative, H(n) is multiplicative too:

$$H(n) = \prod_{i=1}^{k} \sum_{j=0}^{\alpha_i} h(p_i^j) = \prod_{i=1}^{k} \alpha_i p_i^{\alpha_i} = n \prod_{i=1}^{k} \alpha_i.$$

Both $s_2(n)$ and H(n) can be computed easily given factorization of n. It can be found straightforwardly in $O(\sqrt{n})$, with possible speed-up to $O(\sqrt{n}/\log n)$ using precomputed prime tables up to \sqrt{n} .

We are given a string s and a set of forbidden strings A. Two players play a game: if at the beginning of one's turn the current string is empty or belongs to A, the player loses immediately, otherwise, he can erase a symbol either from the beginning of from the end of the string. Find winning player for several substrings of sas starting strings.

If the string s were small, the following simple $O(n^2)$ solution would suffice.

▲□▶ ▲圖▶ ▲臣▶ ★臣▶ 三臣 - のへで

If the string *s* were small, the following simple $O(n^2)$ solution would suffice. Denote $w_{l,r}$ the outcome of the game if the game is played on the substring with positions s[l; r). Values of $w_{l,r}$ are determined easily using DP:

- 3 Win because $w_{l+1,r}$ or $w_{l,r-1}$ is a forced lose (e.g. [1; 3), [1, 5))
- Solution Lose because $w_{l+2,r}$ and $w_{l,r-2}$ are loses (e.g. [1; 6))

It can easily be shown that in all other cases $w_{l,r}$ is indeed equal to $w_{l+1,r-1}$.

Knowing that, we will do the following: store two adjacent diagonals of the table, and gradually move them to the up and to the right while processing all the cases the elements change and answering queries off-line. We assume that we know all occurences of elements of A as substrings of s.

(日) (四) (日) (日) (日)

Knowing that, we will do the following: store two adjacent diagonals of the table, and gradually move them to the up and to the right while processing all the cases the elements change and answering queries off-line. We assume that we know all occurences of elements of A as substrings of s.

For each query and each occurence store the index of diagonal it is concerned.

ション ふゆ く 山 マ チャット しょうくしゃ

Knowing that, we will do the following: store two adjacent diagonals of the table, and gradually move them to the up and to the right while processing all the cases the elements change and answering queries off-line. We assume that we know all occurences of elements of A as substrings of s.

For each query and each occurence store the index of diagonal it is concerned.

- When answering a query, simply access the diagonal's element (we assume that is has been maintained correctly)
- When processing an occurence, change the element of the diagonal to L, and the elements immediately to the up and to the right to W

It suffices to maintain the third condition ($w_{l+2,r} = w_{l,r-2} = L$). We cannot scan the diagonals and find these situations explicitly.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

It suffices to maintain the third condition $(w_{l+2,r} = w_{l,r-2} = L)$. We cannot scan the diagonals and find these situations explicitly. However, we can notice that these situations arise only as a result of a forced lose in the diagonal which is filled with W by default.

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへの

Statement

$$T = O(n\sqrt{L}).$$

Proof

Let all elements of A be unique. Denote $L = \sum_{a_i \in A} |a_i|$. We use Aho-Corasick to find all occurences in time O(n + L + T). Therefore, it suffices to estimate T.

Statement

 $T = O(n\sqrt{L}).$

Proof

The total number of occurences of strings of length I does not exceed n. Thus, T does not exceed $n \times ($ number of different lengths of elements of A).

Let all elements of A be unique. Denote $L = \sum_{a_i \in A} |a_i|$. We use Aho-Corasick to find all occurences in time O(n + L + T). Therefore, it suffices to estimate T.

Statement

 $T = O(n\sqrt{L}).$

Proof

The total number of occurences of strings of length I does not exceed n. Thus, T does not exceed $n \times ($ number of different lengths of elements of A).

The number of different lengths is maximal if lengths are 1, 2, ..., and is $O(\sqrt{L})$, which implies the statement.

Let all elements of A be unique. Denote $L = \sum_{a_i \in A} |a_i|$. We use Aho-Corasick to find all occurences in time O(n + L + T). Therefore, it suffices to estimate T.

Statement

$$T=O(n\sqrt{L}).$$

Proof

The total number of occurences of strings of length I does not exceed n. Thus, T does not exceed $n \times ($ number of different lengths of elements of A).

The number of different lengths is maximal if lengths are 1, 2, ..., and is $O(\sqrt{L})$, which implies the statement.

This concludes the analysis of the problem. The resulting solution has complexity $O(L + n\sqrt{L})$.

Let us try to make array non-decreasing, and then repeat the procedure for the reversed array.

F. Almost sorted array

Given an array of numbers, we have to erase at most one element so that to make the array becomes either non-decreasing or non-increasing.

Let us try to make array non-decreasing, and then repeat the procedure for the reversed array.

Suppose that we have erased a_i . The resulting array is non-decreasing if first i - 1 elements are sorted, last n - i elements are sorted, and $a_{i-1} \leq a_{i+1}$ (if i = 1 or i = n, this condition is redundant). Find the longest sorted prefix and suffix, then try to erase each element. This makes for a simple O(n) solution.

Let's ignore lex-min requirement for now. How to build any optimal coloring?

If we add edges between pairs of cells with $|x_1 - x_2| = a$,

 $|y_1 - y_2| = b$, we obtain a bipartite graph. We can construct a convenient partition: first *a* rows are in the first part, next *a* rows are in the second part and so on.

うして ふゆう ふほう ふほう うらつ

I. Chess puzzle

C

Let's ignore lex-min requirement for now. How to build any optimal coloring?

I ○●○○○ Μ

If we add edges between pairs of cells with $|x_1 - x_2| = a$, $|y_1 - y_2| = b$, we obtain a bipartite graph. We can construct a convenient partition: first *a* rows are in the first part, next *a* rows are in the second part and so on.

If n = m = 5, a = 2, the partition looks as follows:

| 1 | 1 | 1 | 1 | 1 |
|---|---|---|---|---|
| 1 | 1 | 1 | 1 | 1 |
| 2 | 2 | 2 | 2 | 2 |
| 2 | 2 | 2 | 2 | 2 |
| 1 | 1 | 1 | 1 | 1 |

Flip the colors of all cells in the second part. Now we have to maximize number of adjacent pairs with the *same* color.

▲□▶ ▲□▶ ▲□▶ ▲□▶ ▲□ ● ● ●

This can be done using min-cut:

add source and sink

- add source and sink
- add edges with capacity 1 between adjacent pairs of cells (in both directions)

▲□▶ ▲□▶ ▲三▶ ▲三▶ 三三 のへで

- add source and sink
- add edges with capacity 1 between adjacent pairs of cells (in both directions)
- $\bullet\,$ add edges with capacity ∞ from source to cells which are initially colored black (accounting for flipping colors of the second part)

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ●

- add source and sink
- add edges with capacity 1 between adjacent pairs of cells (in both directions)
- $\bullet\,$ add edges with capacity ∞ from source to cells which are initially colored black (accounting for flipping colors of the second part)
- $\bullet\,$ add edges with capacity ∞ from cells which are initially colored white to sink

◆□▶ ◆□▶ ◆□▶ ◆□▶ ● ● ●

- add source and sink
- add edges with capacity 1 between adjacent pairs of cells (in both directions)
- add edges with capacity ∞ from source to cells which are initially colored black (accounting for flipping colors of the second part)
- $\bullet\,$ add edges with capacity ∞ from cells which are initially colored white to sink

Any S - T cut corresponds to coloring (S's part — black, T's part — white), and its capacity is exactly the number of points of different color. Minimal S - T cut corresponds to coloring with maximal number of same-colored adjacent pairs.

If actual color (that is, without flipping) of the current cell is B, then we can't minimize it further. Add the edge between the cell and source/sink (depending on the part of the cell), as if the color were fixed from the beginning.

If color of the current cell is W, then we should try to change it to B. Assume that colors of all earlier cells are fixed by adding edges from source/to sink.

Suppose that changing is possible. Add edge between the cell and source/sink (depending on whether the cell's color was flipped or not). The value of min-cut should not increase; equivalently, it should be impossible to push one unit of flow after adding the edge. It means that the cell and sink/source should not be connected in the residual network.

М

To sum up, we have to add edges to the network and for each vertex remember whether it is reachable from the source, and whether sink is reachable from it using edges of residual network.

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQで

To sum up, we have to add edges to the network and for each vertex remember whether it is reachable from the source, and whether sink is reachable from it using edges of residual network. To do this, after adding every edge run DFS from the cell adjacent to it; visibility markings should not be cleared between runs.

ション ふゆ く 山 マ チャット しょうくしゃ

To sum up, we have to add edges to the network and for each vertex remember whether it is reachable from the source, and whether sink is reachable from it using edges of residual network. To do this, after adding every edge run DFS from the cell adjacent to it; visibility markings should not be cleared between runs. This process takes $O(n^2)$ total time, which means complexity depends entirely on the max-flow algorithm used.
