Sums

Problem C Sums

Submits: 241 Accepted: 68

First solved by: University of Zagreb (Stjepan Glavina, Ivan Katanic, Gustav Matula) 00:07:56

Author: Damian Straszak

Jagiellonian University

CERC 2014: Presentation of solutions

Use the formula:

$$k + (k + 1) + ... + (k + d - 1) = \frac{(2k + d - 1)d}{2}$$

To end up with equation:

$$(2k+d-1)d=2N$$

Want to solve it for $k, d \in \mathbb{N}$, $d \geq 2$.

Jagiellonian University

$$(2k+d-1)d=2N$$

- Check all divisors $d \ge 2$ of 2N.
- Easy to do in $O(\sqrt{N})$ time.
- "IMPOSSIBLE" if and only if $N = 2^r$

Wheels

Problem D Wheels

We construct a graph of n nodes – nodes x and y are connected by an edge iff the wheels x and y touch each other.

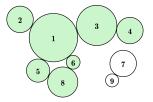

We construct a graph of n nodes – nodes x and y are connected by an edge iff the wheels x and y touch each other.

Machine not jammed \Leftrightarrow The graph is bipartite.

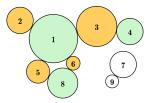

We construct a graph of n nodes – nodes x and y are connected by an edge iff the wheels x and y touch each other.

If a wheel is turning, the whole connected component is turning.

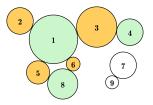

We construct a graph of n nodes – nodes x and y are connected by an edge iff the wheels x and y touch each other.

We compute the connected component of node 1. Wheels of even distance are turning clockwise, other – counterclockwise

We construct a graph of *n* nodes - nodes x and y are connected by an edge iff the wheels x and y touch each other.

Every point on the boundary is travelling the same distance per minute exactly $2\pi R_1$. Therefore the wheel *i* makes R_1/R_i turns per minute.

Problem I Bricks

Problem:

You are given three strings, some of the characters are turned to question marks. In how many ways you can substitute question marks with letters so that the three strings are in strict lexicographical order?

Jagiellonian University

CERC 2014: Presentation of solutions

First: to make things easier, if the strings are not of the equal length, pad them with a'-1.

HEORETICAL OMPUTER C I E N C E

Jagiellonian University

CERC 2014: Presentation of solutions

First: to make things easier, if the strings are not of the equal length, pad them with a'-1.

For each string, for each its suffix, precompute the number of different ways it can be substituted (basically $26^{<number of ? on the suffix>}$).

Jagiellonian University

CERC 2014: Presentation of solutions

First: to make things easier, if the strings are not of the equal length, pad them with a'-1.

For each string, for each its suffix, precompute the number of different ways it can be substituted (basically $26^{<\text{number of }?}$ on the suffix>).

For each suffix, precompute the number of ways the first and the second string can be substituted (ignoring the third string) so that these two suffixes are in strict lexicographical order.

Do the analogous precomputing for the second and the third string.

HEORETICAL COMPUTER COMPUTER Laniellonian University

Jagiellonian University

CERC 2014: Presentation of solutions

There must be some difference on i-th position – there are three cases:

- *A*[*i*] < *B*[*i*] < *C*[*i*],
- A[i] < B[i] = C[i],
- A[i] = B[i] < C[i].

Jagiellonian University

CERC 2014: Presentation of solutions

There must be some difference on *i*-th position – there are three cases:

- A[i] < B[i] < C[i],
- A[i] < B[i] = C[i],
- A[i] = B[i] < C[i].

The number of ways the prefix can be substituted is simply $_{26}$ <number of positions with three ?> before the first position where non-? characters are different, and 0 after this position.

There must be some difference on *i*-th position – there are three cases:

- *A*[*i*] < *B*[*i*] < *C*[*i*],
- A[i] < B[i] = C[i],
- A[i] = B[i] < C[i].

The number of ways the prefix can be substituted is simply $26^{<\text{number of positions with three }?>}$ before the first position where non-? characters are different, and 0 after this position. The number of ways the suffixes can be substituted can be easily computed from precomputed values.

There must be some difference on *i*-th position – there are three cases:

- A[i] < B[i] < C[i],
- A[i] < B[i] = C[i],
- A[i] = B[i] < C[i].

The number of ways the prefix can be substituted is simply $26^{<\text{number of positions with three }?>}$ before the first position where non-? characters are different, and 0 after this position. The number of ways the suffixes can be substituted can be easily computed from precomputed values.

The whole solution runs in O(n) time.

First solved by: University of Warsaw (Paweł Kura, Bartosz Tarnawski, Kamil Żyła) 01:32:38

Author: Arkadiusz Pawlik

Jagiellonian University

CERC 2014: Presentation of solutions

If we reach a configuration of the form:

$\ldots, 16, 8, 32, \ldots$

then we are stuck.

Jagiellonian University

CERC 2014: Presentation of solutions

The only valid configurations are:

$$(l_1, l_2, ..., l_q, r_s, r_{s-1}, ..., r_1)$$

with

$$l_1 < l_2 < ... < l_q$$
 and $r_s > r_{s-1} > ... > r_1$
 $l_i, r_j \in \{1, 2, 4, 8, ...\}$ for all i, j

HEORETICAL OMPUTER CIENCE

Jagiellonian University

CERC 2014: Presentation of solutions

The algorithm:

- Keep the set of reachable configurations after each step,
- compute the new set by trying two options for every old reachable configuration.

Jagiellonian University

CERC 2014: Presentation of solutions

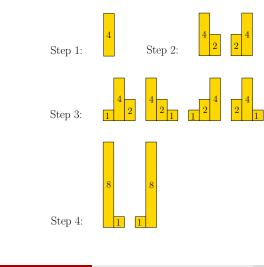

How many valid configurations are there?

- Not many!
- For fixed sum = $l_1 + l_2 + ... + l_q + r_1 + r_2 + ... + r_s \le 2^{13}$
- there are at most 2¹³ valid configurations!

Example: 4, 2, 1, 2

Jagiellonian University

CERC 2014: Presentation of solutions

$$(l_1, l_2, ..., l_q, r_s, r_{s-1}, ..., r_1)$$

How to represent a configuration?

- at each step the sum = $l_1 + l_2 + ... + l_q + r_1 + r_2 + ... + r_s$ is fixed,
- it is enough to store $(I_1, I_2, ..., I_q)$,

• or even
$$I = I_1 + I_2 + ... + I_q$$
,

• only one 32-bit variable!

- Worst case $\approx 2^{13} \cdot 1000$ unit operations per test case.
- Recovering the answer: reverse the algorithm...

If the adversary can destroy at most k items, what is our total gain?

Jagiellonian University

CERC 2014: Presentation of solutions

If the adversary can destroy at most k items, what is our total gain?

Let us change the game slightly. Instead of one item at a time, we give The Imp our whole strategy:

Jagiellonian University

CERC 2014: Presentation of solutions

If the adversary can destroy at most k items, what is our total gain?

Let us change the game slightly. Instead of one item at a time, we give The Imp our whole strategy:

A strategy is the sequence (s_1, \ldots, s_{k+1}) of items. The Imp chooses which item we can keep, and we pay for this one and all the previous ones.

If the adversary can destroy at most k items, what is our total gain?

Let us change the game slightly. Instead of one item at a time, we give The Imp our whole strategy:

A strategy is the sequence (s_1, \ldots, s_{k+1}) of items. The Imp chooses which item we can keep, and we pay for this one and all the previous ones.

This does not help us (of course), but also doesn't help The Imp, who already knew the strategy.

Key observation:

We can assume that for the optimal strategy s_1, \ldots, s_n we have $value(s_1) \leq value(s_2) \leq \ldots \leq value(s_{k+1})!$

Jagiellonian University

CERC 2014: Presentation of solutions

Key observation:

We can assume that for the optimal strategy s_1, \ldots, s_n we have $value(s_1) \leq value(s_2) \leq \ldots \leq value(s_{k+1})!$

This can be proven by "exchange" argument:

If $s_i > s_{i+1}$ and we swap s_i with s_{i+1} , then every Imp's possible move will yield worse result for him (and thus better for us).

So, the optimal strategy is a sequence increasing wrt. value.

Jagiellonian University

CERC 2014: Presentation of solutions

So, the optimal strategy is a sequence increasing wrt. *value*.

With that observation, quite a few strategies work. We will show the arguably easiest to prove – dynamic strategy:

Jagiellonian University

CERC 2014: Presentation of solutions

HEORETICAL OMPUTER CIENCE

Jagiellonian University

CERC 2014: Presentation of solutions

If we want to start the game with picking item *i*, then either:

- Imp lets us have it: value(i) cost(i).
- Imp destroys it: -cost(i) + dp[i+1][q-1].

Of course, Imp will choose worse option.

If we want to start the game with picking item *i*, then either:

- Imp lets us have it: value(i) cost(i).
- Imp destroys it: -cost(i) + dp[i+1][q-1].

Of course, Imp will choose worse option.

If we ignore the item i, then we should never go back to it, so the solution is dp[i+1][q].

If we want to start the game with picking item *i*, then either:

- Imp lets us have it: value(i) cost(i).
- Imp destroys it: -cost(i) + dp[i+1][q-1].

Of course, Imp will choose worse option.

If we ignore the item i, then we should never go back to it, so the solution is dp[i+1][q].

Summing that up: dp[i][q] = max(dp[i+1][q], min(value(i) - cost(i), -cost(i) + dp[i+1][q-1])).Complexity: O(nk). Jagiellonian University CERC 2014: Presentation of solutions 36 / 62 Why $k \leq 9$?

There is also an improved backtrack that works in $O(k! \log n + n \log n)$. It would get an OK as well.

Problem:

You are given a tree on $n \le 1000$ nodes with maximum degree $d \le 10$, and $m \le \binom{n}{2}$ paths (given as their endpoints). You need to find the maximum size edge-disjoint subset of these paths.

Jagiellonian University

CERC 2014: Presentation of solutions

Problem:

You are given a tree on $n \le 1000$ nodes with maximum degree $d \le 10$, and $m \le \binom{n}{2}$ paths (given as their endpoints). You need to find the maximum size edge-disjoint subset of these paths.

Solution:

 $O(n^2 + nd2^d + m)$ bottom-up dynamic programming with maximum matching computation in each node.

Solution:

- Root the tree in any node.
- For each subtree compute (in bottom-up order):
 - the maximum number of disjoint paths within this subtree;
 - which nodes in this subtree are still accessible from its root without using any edge from the above paths.

Jagiellonian University

CERC 2014: Presentation of solutions

Solution:

- Root the tree in any node.
- For each subtree compute (in bottom-up order):
 - the maximum number of disjoint paths within this subtree;
 - which nodes in this subtree are still accessible from its root without using any edge from the above paths.

Key observation:

It is never beneficial to leave two nodes accessible instead of connecting them with a path.

THEORETICAL COMPUTER CIENCE

Jagiellonian University

CERC 2014: Presentation of solutions

• For every child v: if any of the accessible nodes from v's subtree can be connected by a path with u, connect it (at most once per child).

HEORETICAL OMPUTER CIENCE

Jagiellonian University

CERC 2014: Presentation of solutions

- For every child *v*: if any of the accessible nodes from *v*'s subtree can be connected by a path with *u*, connect it (at most once per child).
- Build an auxiliary graph with children as nodes. Two children are connected with an edge if there is a path on the input that connects two accessible nodes from subtrees of these children.

Jagiellonian University

CERC 2014: Presentation of solutions

- For every child *v*: if any of the accessible nodes from *v*'s subtree can be connected by a path with *u*, connect it (at most once per child).
- Build an auxiliary graph with children as nodes. Two children are connected with an edge if there is a path on the input that connects two accessible nodes from subtrees of these children.
- Calculate the maximum matching on the auxiliary graph. There are at most 10 nodes, so a simple exponential time algorithm (backtracking or DP on all subsets) is sufficient.

First solved by: Charles University in Prague (Pavol Rohár, Jakub Šafin, Tomáš Šváb) 02:38:09

Author: Bartosz Walczak

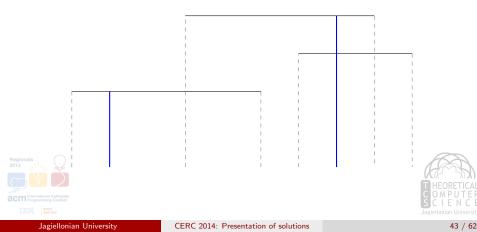

Jagiellonian University

CERC 2014: Presentation of solutions

Problem (slightly rephrased):

You are given $n \leq 300$ horizontal segments $(a_i, d_i) - (b_i, d_i)$. You have to draw some vertical segments, starting at the OX axis, in such a way that they touch (or intersect) all horizontal segments and have the minimal total length.

Observation: it is always OK to draw horizontal segments only at some a_i .

Solution: dynamic programming with $O(n^2)$ states and O(n) time per state.

DP[i][j] = minimal length of vertical segments intersecting horizontal segments fully contained in (a_i, a_j) interval.

- full[i] cost of creating p_i.
- half[i] cost of creating half of p_i.

How can we obtain first half of p_i ?

A A C C A	A	С	С	A	A	
-----------	---	---	---	---	---	--

- by adding the first letter to half of trim(i): half[i] = half[trim(i)] + 1,
- by synthesizing palindrome p_l that is a prefix of half(p_i) and adding some letters at the end: half[i] = full[l] + length(i)/2 - length(l).

If we know the cost of synthesizing all palindromes in the word, it is easy to compute the cost of the whole word.

We can only obtain the word from its palindrome subword – we simply check all of them.

This solution has complexity $O(n \log n)$. The log *n* factor comes from searching for prefix palindromes (not trivial, but quite easy).
